

Laboratory Exercise 4: Iterative Statements I

Learning Outcomes:

- Implement comparing sum of factors using iterative and conditional statements in C.

Exercise Details

Practically all of the programs/apps that run on our computers are iterations one way or another. It is impractical to build a computer program using sequential and conditional statements alone. In C programming there are generally two classification of iterative statements, the pretest iteration and the posttest iteration. Refer to the handouts for the details regarding these iterative statements.

Problem:

- Ask for 2 positive integer inputs.
- From your integer inputs take their sum of factors (excluding itself).
- Compare their sum of factors if they are equal, greater than (or less than) the other.

Example:

```
Integer A: 10
Integer B: 12
Sum of factors for A: 8
Sum of factors for B: 16
The Sum of factors for Integer A < Integer B
```

Write all your code on function main, refer to the code format below.

```
#include <stdio.h>

int main()
{
    //Write your code here!
}
```
